HAMILTON-JACOBI-BELLMAN EQUATION Definitions

Let us define dynamics:

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}, \mathbf{u}) \tag{1}$$

with initial conditions $\mathbf{x}(0)$.

Additionally we define *control policy* as:

$$\mathbf{u} = \pi(\mathbf{x}, t) \tag{2}$$

To connect with the previous ways we talked about control, we can say that choosing different control gains and different feed-forward control amounts to choosing a different control policy.

HAMILTON-JACOBI-BELLMAN EQUATION

Cost, optimal cost

Let J be an additive cost function:

$$J(\mathbf{x}_0, \pi(\mathbf{x}, t)) = \int_0^\infty g(\mathbf{x}, \mathbf{u}) dt$$
 (3)

where $g(\mathbf{x}, \mathbf{u})$ is instantaneous cost and $\mathbf{x}_0 = \mathbf{x}(0)$ is the initial conditions. Notice that J depends on \mathbf{x}_0 rather than $\mathbf{x}(t)$, since initial conditions and control policy completely define the trajectory of the system $\mathbf{x}(t)$.

Let J^* be the optimal (lowest possible) cost. In other words:

$$J^*(\mathbf{x}_0) = \inf_{\pi} J(\mathbf{x}_0, \pi(\mathbf{x}, t))$$
 (4)

Optimal cost is attained when optimal policy is attained: $\pi = \pi^*(\mathbf{x}, t)$

HAMILTON-JACOBI-BELLMAN EQUATION

Differentiating optimal cost

Since $J^*(\mathbf{x}_0)$ does not depend on t, its full derivative is zero:

$$\frac{dJ^*(\mathbf{x}_0)}{dt} = 0 \tag{5}$$

At the same time, we can expand the full derivative as follows:

$$\frac{dJ^*}{dt} = \frac{\partial J^*}{\partial \mathbf{x}} \dot{\mathbf{x}} + \frac{\partial J^*}{\partial t} = 0 \tag{6}$$

Observe that $\frac{\partial J^*}{\partial t} = g(\mathbf{x}, \mathbf{u})$, and $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}, \mathbf{u})$. Therefore:

$$\frac{\partial J^*}{\partial \mathbf{x}} \mathbf{f}(\mathbf{x}, \mathbf{u}) + g(\mathbf{x}, \mathbf{u}) = 0 \tag{7}$$

HAMILTON-JACOBI-BELLMAN EQUATION

With this, we can formulate Hamilton-Jacobi-Bellman equation (HJB):

$$\min_{\mathbf{u}} \left[g(\mathbf{x}, \mathbf{u}) + \frac{\partial J^*}{\partial \mathbf{x}} \mathbf{f}(\mathbf{x}, \mathbf{u}) \right] = 0$$
 (8)

This can be loosely interpreted as follows: the value in square brackets is $\dot{J}(\mathbf{x}_0,\pi)$, which is equal to 0 when $\pi=\pi^*(\mathbf{x},t)$, and is positive otherwise (in the small vicinity of π^*), as $J(\mathbf{x}_0, \pi^*)$ is smaller than any $J(\mathbf{x}_0, \pi), \ \pi^* \neq \pi$.

We can find control that delivers minimum to the function (8):

$$u^* = \underset{\mathbf{u}}{\operatorname{arg\,min}} \left[g(\mathbf{x}, \mathbf{u}) + \frac{\partial J^*}{\partial \mathbf{x}} \mathbf{f}(\mathbf{x}, \mathbf{u}) \right]$$
(9)

ALGEBRAIC RICCATI HJB for LTI

For LTI, dynamics is:

$$\dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{u} \tag{10}$$

We can choose quadratic cost:

$$g(\mathbf{x}, \mathbf{u}) = \mathbf{x}^{\top} \mathbf{Q} \mathbf{x} + \mathbf{u}^{\top} \mathbf{R} \mathbf{u}$$
 (11)

Then HJB becomes:

$$\min_{\mathbf{u}} \left[\mathbf{x}^{\top} \mathbf{Q} \mathbf{x} + \mathbf{u}^{\top} \mathbf{R} \mathbf{u} + \frac{\partial J^{*}}{\partial \mathbf{x}} (\mathbf{A} \mathbf{x} + \mathbf{B} \mathbf{u}) \right] = 0$$
 (12)

where
$$\mathbf{Q} = \mathbf{Q}^{\top} \geq 0$$
 and $\mathbf{R} = \mathbf{R}^{\top} > 0$.

Algebraic Riccati

HJB for LTI, part 2

There is a theorem that says that for LTI with quadratic cost, J^* has the form:

$$J^* = \mathbf{x}^\top \mathbf{S} \mathbf{x} \tag{13}$$

where $\mathbf{S} = \mathbf{S}^{\top} \geq 0$.

Then HJB becomes:

$$\min_{\mathbf{u}} \ \left[\mathbf{x}^{\top} \mathbf{Q} \mathbf{x} + \mathbf{u}^{\top} \mathbf{R} \mathbf{u} + \mathbf{x}^{\top} \mathbf{S} (\mathbf{A} \mathbf{x} + \mathbf{B} \mathbf{u}) + (\mathbf{A} \mathbf{x} + \mathbf{B} \mathbf{u})^{\top} \mathbf{S} \mathbf{x} \right] = 0$$

Simplifying, we get:

$$\min_{\mathbf{u}} \ \left[\mathbf{u}^{\top} \mathbf{R} \mathbf{u} + \mathbf{x}^{\top} (\mathbf{Q} + \mathbf{S} \mathbf{A} + \mathbf{A}^{\top} \mathbf{S}) \mathbf{x} + \mathbf{x}^{\top} \mathbf{S} \mathbf{B} \mathbf{u} + \mathbf{u}^{\top} \mathbf{B}^{\top} \mathbf{S} \mathbf{x} \right] = 0$$

ALGEBRAIC RICCATI

Linear Quadratic Regulator

Finding partial derivative of the HJB with respect to **u** and setting it to zero (as it is an extreme point) we get:

$$2\mathbf{u}^{\mathsf{T}}\mathbf{R} + 2\mathbf{x}^{\mathsf{T}}\mathbf{S}\mathbf{B} = 0 \tag{14}$$

This expression can be transposed and **u** separated:

$$\mathbf{u} = -\mathbf{R}^{-1}\mathbf{B}^{\mathsf{T}}\mathbf{S}\mathbf{x} \tag{15}$$

This is the desired control law. We can see that it is proportional. We can re-write it as:

$$\mathbf{u} = -\mathbf{K}\mathbf{x} \tag{16}$$

where $\mathbf{K} = \mathbf{R}^{-1}\mathbf{B}^{\mathsf{T}}\mathbf{S}$ is the controller gain. This control law is called Linear Quadratic Regulator (LQR).

ALGEBRAIC RICCATI

Substituting found control law into the HJB, we find:

$$\min_{\mathbf{u}} \left[\mathbf{x}^{\top} (\mathbf{Q} + \mathbf{S} \mathbf{A} + \mathbf{A}^{\top} \mathbf{S}) \mathbf{x} + \mathbf{x}^{\top} \mathbf{S} \mathbf{B} \mathbf{R}^{-1} \mathbf{R} \mathbf{R}^{-1} \mathbf{B}^{\top} \mathbf{S} \mathbf{x} - \mathbf{x}^{\top} \mathbf{S} \mathbf{B} \mathbf{R}^{-1} \mathbf{B}^{\top} \mathbf{S} \mathbf{x} \right] = 0$$

$$(17)$$

Simplifying, we get:

$$\mathbf{x}^{\top}(\mathbf{Q} + \mathbf{S}\mathbf{A} + \mathbf{A}^{\top}\mathbf{S} - \mathbf{S}\mathbf{B}\mathbf{R}^{-1}\mathbf{B}^{\top}\mathbf{S})\mathbf{x} = 0$$
 (18)

which would hold for all \mathbf{x} iff:

$$\mathbf{Q} - \mathbf{S}\mathbf{B}\mathbf{R}^{-1}\mathbf{B}^{\mathsf{T}}\mathbf{S} + \mathbf{S}\mathbf{A} + \mathbf{A}^{\mathsf{T}}\mathbf{S} = 0$$
 (19)

This is the Algebraic Riccati equation.

Algebraic Riccati

Numerical methods

There are a number of ways to solve LQR:

- In MATLAB there is a function [K,S,P] = lqr(A,B,Q,R), where P=eig(A-B*K)
- In Python, there is S = scipy.linalg.solve_continuous_are(A,B,Q,R)
- In Drake (by MIT and Toyota Research) there is a function (K,S) = LinearQuadraticRegulator(A,B,Q,R)
